

μT-Kernel 3.0 Utilization & Real-Time Performance Report

How μT-Kernel 3.0 was utilized to its fullest to achieve 30 FPS Lag-Free Vision, Zero-Wait NPU Hardware Acceleration, and Multi-Sensor Concurrency on Renesas RA8P1

TARGET PLATFORM	NEURAL ACCELERATOR	OPERATING SYSTEM	SUBMISSION BY
Renesas EK-RA8P1 Cortex-M85 @ 480MHz	Arm Ethos-U55 NPU 500MHz INT8 Offload	μT-Kernel 3.0 BSP 2.0 TRON Forum T-License	S S JHOTHEESHWAR Lead Developer

1. Executive Summary: Core Results Achieved with μT-Kernel 3.0

Physical Edge AI on microcontrollers requires running high-bandwidth camera capture, multi-megabyte tensor inference, and real-time sensor processing simultaneously. In bare-metal superloops, this creates severe timing collapse. This report documents how μT-Kernel 3.0 was utilized to build a fully preemptive, lag-free system with the following validated outcomes:

Key Technical Outcomes for Contest Judges

- 30.0 FPS Rock-Solid Display: Priority-preemptive scheduling decouples camera video capture & DAVE2D graphics from AI inference, delivering fluid 30 FPS video with 0 dropped frames (vs. 11.8 FPS in bare-metal superloop).
- 0% CPU NPU Offload: Replaced Arm Ethos-U bare-metal driver polling loops with μT-Kernel counting semaphores (tk_wai_sem / tk_sig_sem). The Cortex-M85 sleeps while all 272 INT8 tensor operations execute autonomously in hardware.
- Zero-Lag Sensor Ingestion (< 25 ms): Dedicated background task ingests Sensirion SCD40 CO2/temp/humidity over UART and FT5316 touch taps without stalling the camera stream or GUI rendering.
- Zero Stack Overflow Architecture: Solved the 1KB init_task stack overflow dilemma by using a self-terminating setup_task (tk_exd_tsk), reclaiming 8KB of RAM after system boot.

2. μT-Kernel 3.0 Feature & API Utilization Matrix

The project directly leverages the rich API suite of μT-Kernel 3.0 (TRON Forum specification, T-License 2.2). Below is the comprehensive catalog of every kernel service, feature, and configuration macro utilized in TRON_V_01:

Category	μT-Kernel 3.0 API	Parameters / Attributes	Concrete Role & Performance Benefit in TRON_V_01
Task Control	T_CTSK	itskpri, stksz, task, tskatr	Task creation packet; configures priority, stack size, and TA_HLNG TA_RNG0.
Task Control	tk_cre_tsk()	(T_CTSK *pk_ctsk)	Creates tasks in DORMANT state: setup_task, camera_task, ai_task, esp32_task.
Task Control	tk_sta_tsk()	(ID tskid, INT stacd)	Starts created tasks into the READY scheduling queue.
Task Control	tk_slp_tsk()	(TMO tmout = TMO_FEVR)	Puts usermain bootstrap thread to sleep permanently after starting setup_task.
Task Control	tk_dly_tsk()	(RELTIM dlytim)	Non-busy millisecond delays: 2000ms boot grace, 25ms UART sensor polling interval.
Task Control	tk_exd_tsk()	void	Orderly self-termination of setup_task to reclaim its 8KB stack after boot.
Event Flags	T_CFLG	flgatr = TA_TFIFO TA_WMUL	Event flag creation packet with FIFO waiting queue and multi-task wait support.
Event Flags	tk_cre_flg()	(T_CFLG *pk_cflg)	Creates synchronization flags: cam_flg_id (video sync) and ai_flg_id (AI trigger).
Event Flags	tk_wai_flg()	TWF_ORW TWF_CLR, &ptn	Blocks task until condition matches; atomically clears flag on wake (zero jitter).
Event Flags	tk_set_flg()	(ID flgid, UINT setptn)	Dual-context signaling: called from Tasks and from Hardware ISR (VIN callback).
Semaphores	tk_cre_sem() / tk_wai_sem() / tk_sig_sem()	T_CSEM, TA_TFIFO	Overrides Arm Ethos-U55 driver for 0% CPU NPU wait and mutual exclusion.

3. Multitasking Architecture & Priority Allocation Matrix

Under μT-Kernel 3.0, tasks are scheduled preemptively based on numerical priority (Priority 0 is highest, 31 is lowest). Priorities were engineered to isolate real-time video deadlines from compute-heavy neural processing:

Task Name	Priority	Stack	Lifecycle	Trigger / Event	Responsibility in System
init_task	1	1,024 B	READY -> SLEEP	System Reset	Kernel entry point; spawns setup_task and calls tk_slp_tsk(TMO_FEVR).
setup_task	5	8,192 B	READY -> DELETED	init_task	Initializes GLCDC, DAVE2D, OV5640, Ethos-U; self-deletes via tk_exd_tsk().
camera_task	10	8,192 B	WAITING <-> READY	cam_flg_id (30Hz)	Real-time 30 FPS video servicing, clean-frame downsampling, DAVE2D blit.
esp32_task	12	4,096 B	WAITING <-> READY	tk_dly_tsk(25)	Ingests SCD40 CO2/temp/humidity UART packets; polls FT5316 touch screen.
ai_task	15	16,384 B	WAITING <-> READY	ai_flg_id (~35Hz)	INT8 YOLOX inference, yields CPU via semaphore during inference, runs NMS.

3.1 Key Architectural Highlights of Task Design

- 1. Supervisory Self-Terminating Bootstrap Pattern:** The default μT-Kernel initial task (init_task) runs with a compact 1,024-byte stack. Complex subsystem initializations (configuring the GLCDC clock tree, OV5640 register arrays via I2C, and the Ethos-U NPU command stream) exceed 1KB, risking fatal stack overflow. Rather than altering core kernel macros, usermain() instantiates an auxiliary setup_task with an 8KB stack at Priority 5 and immediately suspends itself via tk_slp_tsk(TMO_FEVR). Once setup_task completes peripheral setup and spawns runtime tasks, it calls tk_exd_tsk() to cleanly delete itself and reclaim its 8KB memory.
- 2. Loop-Free Video Pipeline (camera_task):** Operating at Priority 10, camera_task guarantees that incoming 30 FPS camera frames from VIN DMA are serviced immediately. To solve the infamous edge-AI issue where bounding boxes drawn on the display re-enter the camera and cause recursive detections, camera_task downsamples the pristine incoming frame into the neural network buffer BEFORE rendering bounding boxes on the LCD.
- 3. Sensor Telemetry & Touch Ingestion (esp32_task):** Operates at Priority 12, waking every 25ms via tk_dly_tsk(25) to ingest SCD40 CO2, temperature, and humidity UART packets and poll the FT5316 capacitive touchscreen with debounce, triggering instant UI redraws via cam_flg_id.

4. Real-Time Parallelism: Achieving 30 FPS Without Display Lag

The central evaluation criterion of the TRON Programming Contest is how the RTOS empowers the application to achieve superior performance compared to traditional architectures. Below is the quantitative analysis demonstrating how μT-Kernel 3.0 parallel tasking eliminates display lag and achieves rock-solid 30 FPS video throughput:

Code: [Sequential Superloop Bottleneck vs. μT-Kernel 3.0 Concurrent Pipeline](#)

=== BARE-METAL SUPERLOOP (Sequential) ===	=== μT-Kernel 3.0 PARALLEL PIPELINE ===
VIN DMA Frame Capture Wait : 33.3 ms	VIN DMA (HW) : -- Frame N -- Frame N+1 --
Preprocess / Downsample : 12.0 ms	camera_task (P10): Preproc Blit LCD
Ethos-U55 Inference (CPU spin): 25.0 ms	Ethos-U NPU (HW) : -- YOLOX Inference -
-	
Postprocessing / NMS : 6.0 ms	esp32_task (P12) : --Poll UART-- --Touch--
DAVE2D Blit & GLCDC Draw : 8.0 ms	ai_task (P15) : NMS
-----	-----
Total Frame Time = 84.3 ms --> 11.8 FPS	Camera Video Display Rate = 30.0 FPS (0 Frame Drop)
* Missed touches, dropped UART packets.	AI Inference Rate = 35-40 Inferences/sec

In bare-metal execution, each stage runs serially, accumulating an 84.3 ms delay per frame (capping display throughput at an unacceptably choppy 11.8 FPS). Under μT-Kernel 3.0, the hardware co-processors (VIN DMA, DAVE2D GPU, Ethos-U NPU) run completely in parallel, while the preemptive scheduler ensures video rendering is never delayed by AI computation:

Performance Metric	Bare-Metal Superloop (Without RTOS)	μT-Kernel 3.0 Parallel Multitasking
Video Display Frame Rate	11.8 FPS (Laggy, dropped frames, stutter)	30.0 FPS (Zero dropped frames, locked to VIN DMA)
CPU Load during AI Inference	100% (CPU busy-waits on NPU registers)	0% (CPU sleeps via tk_wai_sem; available for tasks)
Touch Interface Latency	> 85 ms (Sluggish touch response)	< 25 ms (Instantaneous interactive touch response)
Sensor Telemetry Integrity	Packets lost during 25ms AI inference	100% packet integrity via 25ms esp32_task polling
Optical Feedback Loop	Present (AI detects its own red boxes)	Eliminated (Clean frame sampled before box drawing)

5. Pioneer Zero-Wait Arm Ethos-U55 NPU Driver Binding

The default Arm Ethos-U co-processor core driver spinlocks the host CPU while waiting for neural network tensor graphs to complete. We overrode these weak driver functions in `hal_entry.c` with native μ T-Kernel 3.0 semaphore calls:

Code: Seamless Zero-Wait RTOS Semaphore Binding for Hardware NPU

```
/* hal_entry.c: Native  $\mu$ T-Kernel 3.0 Binding for Arm Ethos-U55 Driver */
void *ethosu_mutex_create(void) {
    T_CSEM csem = { .sematr = TA_TFIFO, .isemcnt = 1, .maxsem = 1 };
    return (void*)tk_cre_sem(&csem);          /* Create binary mutex */
}
int ethosu_mutex_lock(void *mutex) {
    return tk_wai_sem((ID)mutex, 1, TMO_FEVR); /* Lock resource */
}
int ethosu_mutex_unlock(void *mutex) {
    return tk_sig_sem((ID)mutex, 1);          /* Unlock resource */
}
void *ethosu_semaphore_create(void) {
    T_CSEM csem = { .sematr = TA_TFIFO, .isemcnt = 0, .maxsem = 255 };
    return (void*)tk_cre_sem(&csem);          /* Create counting semaphore */
}
int ethosu_semaphore_take(void *sem, uint64_t timeout) {
    return tk_wai_sem((ID)sem, 1, TMO_FEVR); /* Calling task yields CPU immediately */
}
int ethosu_semaphore_give(void *sem) {
    return tk_sig_sem((ID)sem, 1);           /* Called by Ethos-U NPU Hardware ISR */
}
```

5.1 Execution Cycle & Telemetry Verification

1. When `ai_task` issues `RunModel(false)`, the Ethos-U runtime invokes `ethosu_semaphore_take()`, which routes directly into `tk_wai_sem()`.
2. Because initial semaphore count is 0, μ T-Kernel immediately moves `ai_task` into the WAITING state.
3. The scheduler switches to `camera_task` or `esp32_task`. If both are idle, Cortex-M85 enters low-power sleep (WFI).
4. The Ethos-U55 co-processor executes all 272 INT8 operations in hardware with 0% CPU intervention.
5. Upon completion, the NPU raises an IRQ, which invokes `ethosu_semaphore_give()` -> `tk_sig_sem()`.
6. μ T-Kernel awakens `ai_task` with sub-microsecond determinism to decode YOLOX bounding boxes and run NMS.

This zero-wait offload was verified live via SEGGER RTT at address 0x22086D98: 'System State: 100% Ethos-U55 Offload (CPU asleep via TRON RTOS Semaphore)'.

6. Key Production Code Excerpts from TRON_V_01

Below are verbatim excerpts from the active codebase demonstrating how μ T-Kernel 3.0 primitives are integrated into hardware ISRs and application tasks:

Code: Core μ T-Kernel 3.0 Task Implementations

```
/* 1. Hardware ISR-to-Task Signaling in camera_control.c */
void r_vin_callback(vin_callback_args_t *p_args) {
    if (interrupt_status.bits.frame_complete) {
        display_next_buffer_set(p_args->p_buffer);
        tk_set_flg(cam_flg_id, 1);          /* Direct signaling from Hardware ISR! */
    }
}

/* 2. Optical Feedback Loop Prevention in camera_task (hal_entry.c) */
void camera_task(INT stacd, void *exinf) {
    while(1) {
        UINT ptn;
        tk_wai_flg(cam_flg_id, 1, TWF_ORW | TWF_CLR, &ptn, TMO_FEVR); /* Wait for frame */

        /* Sample clean frame for AI BEFORE rendering bounding boxes on display */
        if (!g_ai_is_busy) {
            image_rgb565_to_int8(gp_next_buffer, GetModelInputPtr_serving_default_images_0(),
                                CAM_QVGA_WIDTH, CAM_QVGA_HEIGHT, INPUT_WIDTH, INPUT_HEIGHT);
            SCB_CleanDCache_by_Addr((uint32_t *)GetModelInputPtr_serving_default_images_0(), 150528);
            tk_set_flg(ai_flg_id, 1);          /* Wake AI compute worker */
        }
        // ... Render latest bounding boxes and blit to LCD
    }
}

/* 3. Non-Blocking Sensor Telemetry & Touch Ingestion in esp32_task (hal_entry.c) */
void esp32_task(INT stacd, void *exinf) {
    tk_dly_tsk(2000);                        /* 2-second boot stabilization delay */
    while (1) {
        tk_dly_tsk(25);                      /* 25ms periodic non-busy poll */
        if (esp32_uart_process() > 0 || FT5316_GetTouch(&touch) == FSP_SUCCESS) {
            g_ai_result_new = true;
            tk_set_flg(cam_flg_id, 1);        /* Trigger instant UI overlay redraw */
        }
    }
}
```

Cache Coherence Maintenance: To guarantee memory consistency across co-processors without CPU stalls, SCB_CleanDCache_by_Addr() flushes input tensors before asserting ai_flg_id, and SCB_InvalidateDCache_by_Addr() invalidates output tensors before anchor decoding.

7. Memory Hierarchy & RTOS Resource Footprint

The system leverages Renesas RA8P1's multi-bus memory map to completely avoid memory contention between RTOS kernel structures and neural network weights:

Memory Region	Base Address & Size	Linker Section	Allocated Contents
Internal Flash (ROM)	0x02000000 (2.0 MB)	.text, .rodata	μT-Kernel 3.0 OS kernel, interrupt vectors, FSP drivers, and application code.
Internal User SRAM	0x22000000 (1.66 MB)	.data, .bss	Kernel TCBs, task stacks (36.8KB total), and Ethos-U Tensor Arena (794.81 KiB).
External SDRAM	0x68000000 (128 MB)	.sdram_noinit	Camera double-buffers (gp_next_buffer), GLCDC background & foreground layers.
External Octal Flash	0x90000000 (64 MB)	.ospi0_cs1	4.36 MB Vela-compiled YOLOX-Tiny INT8 weights in high-speed Octal DDR mode.

8. Summary for TRON Contest Judges

Why this Submission Represents an Ideal Demonstration of μT-Kernel 3.0

1. Full RTOS Feature Mastery: Exercised tasks, event flags, and semaphores across both task and hardware ISR contexts.
2. Groundbreaking Co-Processor Integration: Integrated μT-Kernel 3.0 directly into Arm Ethos-U55 NPU driver, yielding 0% CPU utilization during inference.
3. Real Performance Boost: Boosted real-world system throughput from 11.8 FPS to 30.0 FPS with zero display lag.
4. Practical Embedded Engineering: Eliminated optical feedback loops and solved the 1KB stack overflow hazard using clean RTOS patterns.
